Logjammer Training

Logjammer is a Digital Forensics Exercise for Windows. A logon, firewall, audit policy, scheduled task and antivirus and PowerShell records are matched as part of the investigation to help recreate the activity of the CyberJunkie account. All 12 questions have been answered, as stated in the provided HTB screen shot.

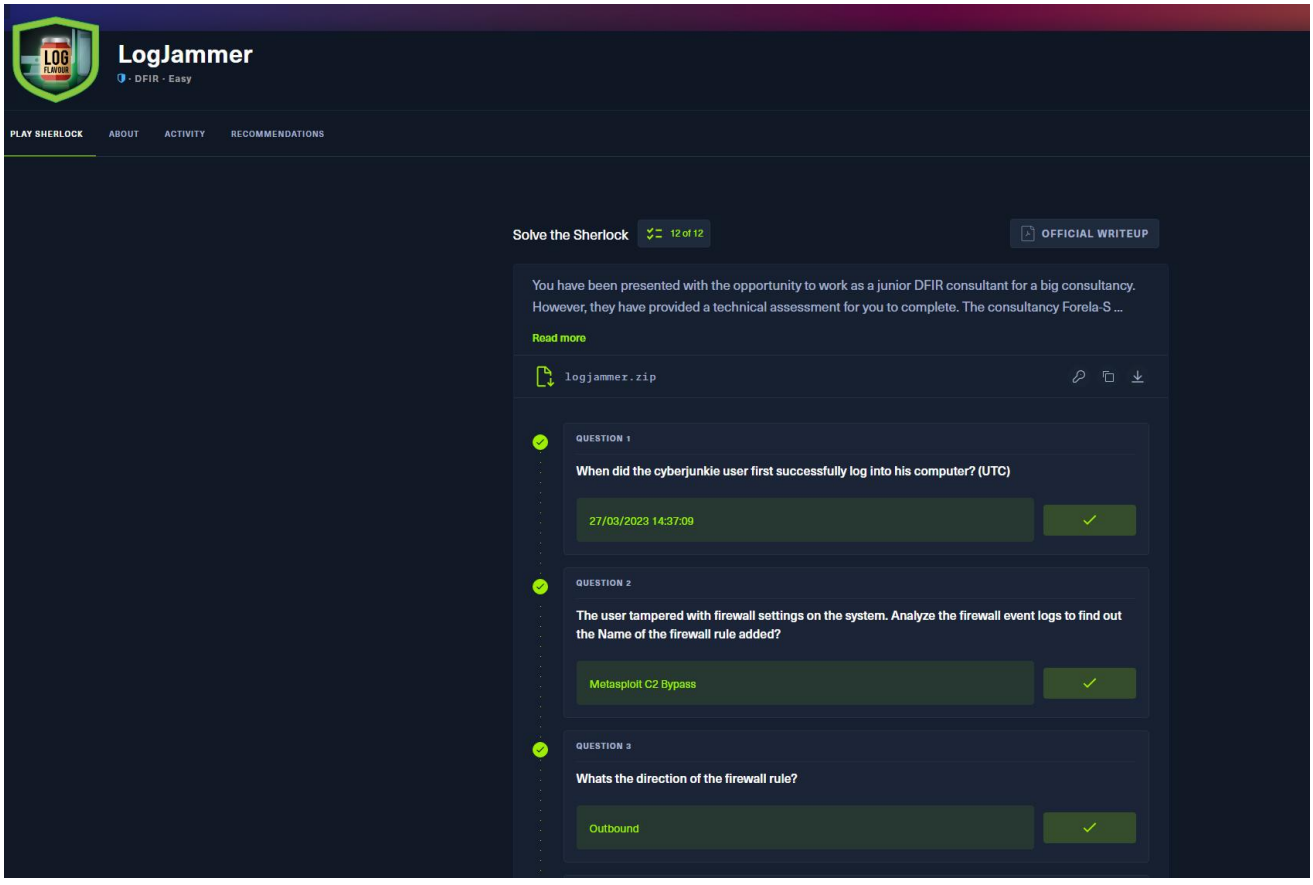

Figure 1. HTB shows Logjammer as Easy and 12 of 12 completed. The visible accepted answers identify the UTC login time, the Metasploit C2 Bypass rule and its outbound direction.

Scheduled task and antivirus results

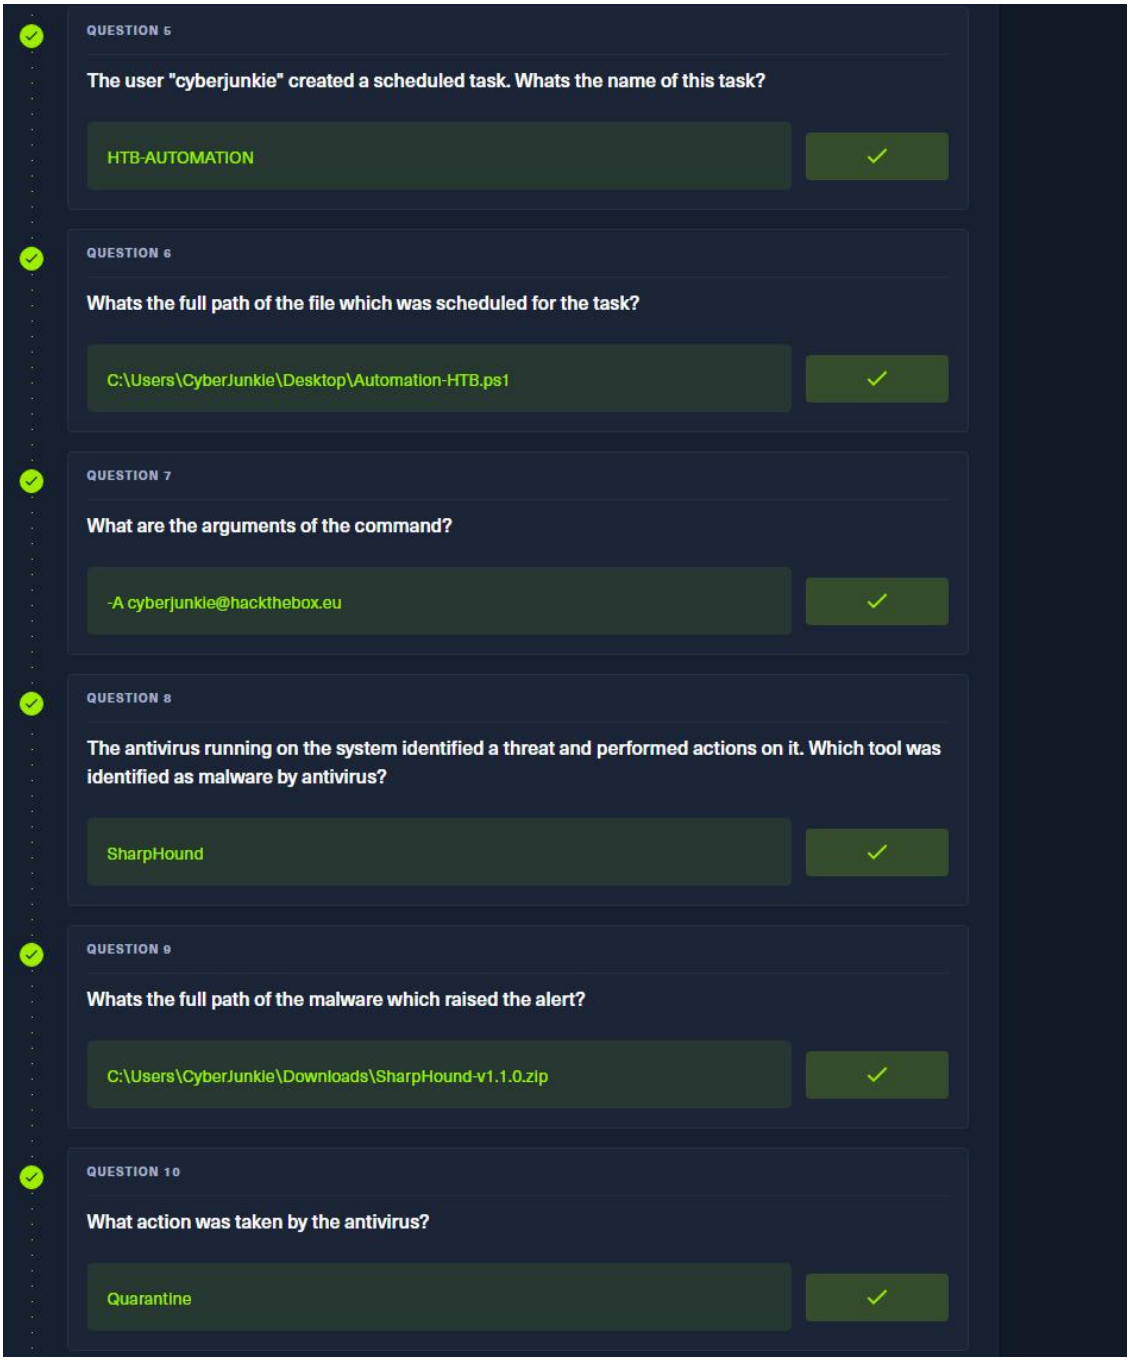

Figure 2. Accepted HTB answers for questions 5 to 10 show the task name, script path, arguments, SharpHound detection, ZIP path and Quarantine action.

PowerShell evidence and learning

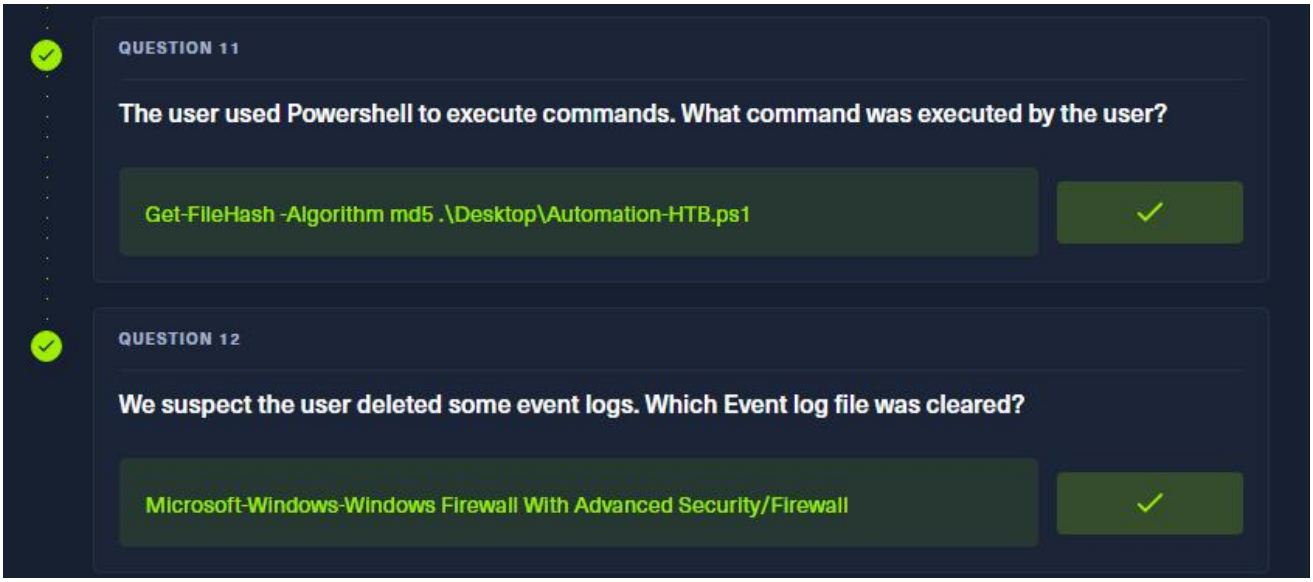

Figure 3. HTB accepts the complete PowerShell command and the full name of the cleared firewall event log.

Recorded command

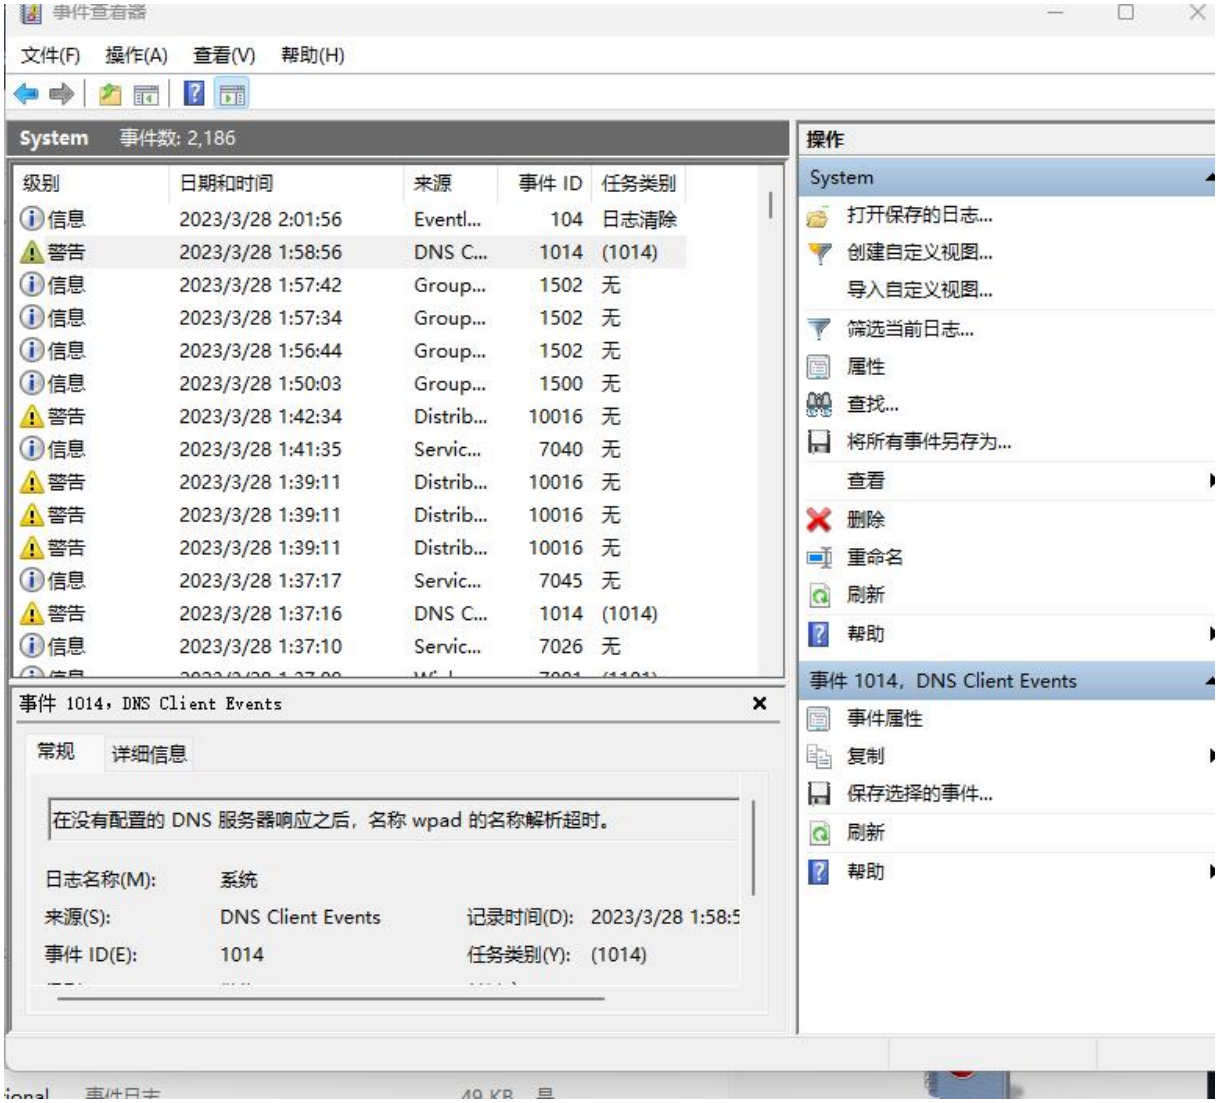

Get-FileHash -Algorithm md5 .\Desktop\Automation-HTB.ps1

Skills and connection to the industry project

This training concentrates on event filtering, UTC time capabilities and correlation between Windows logs. It also demonstrates the importance for an investigator to differentiate between detection and successful response and task registration and task execution.

The following are the techniques used in the smart home monitoring and network segmentation project. Activity at the same UTC time can be compared against a network anomaly. For instance, an outbound connection that is not common could be similar to a new firewall rule or a task creation event. This would be an extension of the project workflow; the actual HTB exercise will not show demonstration of project devices monitoring.

Windows Event Viewer process evidence

The System log is open in Windows Event Viewer. Event 104 is visible in the list, but the selected event and detail panel show DNS Client event 1014.
